ABSTRACT

The object of this work is biosynthesizing AgNPs from extracts of *Cyperus* sp. galingale rhizomes, studying their characteristics using UV-visible spectroscopy, AFM, SEM, FTIR, and EDX analyses and testing their anticancer activity (*in vitro*) against L20B cell line. Biosynthesizing AgNPs using various plants is considered eco-friendly, cheap, energy saving and reproducible compared with non-green methods. UV-Visible spectrum checked the surface plasmon resonance of AgNPs at 410-420 nm. FT-IR exhibited that the presence of carbonyl and hydroxyl groups in the extract of *Cyperus* sp. can reduce and stabilize AgNPs. EDX, SEM, and AFM analyses were applied to confirm the nature, morphology and topography of the biosynthesized AgNPs. AgNPs are spherical or irregular in shape with the average diameter of hot extract-AgNPs is 56.31 nm in comparison with cold extract-AgNPs is 92.53 nm. The hot extract-AgNPs paly a suitable role against mouse cell line (L20B) which have receptors for polioviruses better than the cold extract-AgNPs.

Keywords: SEM, EDS, Green nanotechnology, Galingale, L20B.

INTRODUCTION

The synthesis of metallic nanoparticles has become an important issue in recent decades due to their various beneficial and unique properties and biomedical and industrial applications ¹. Nanotechnology is seeking to synthesize nanoparticles have substantial biomedical applications because of their unique characteristics and their green nature due to using some medicinal plants as...
a reducer agent in the biosynthesis of metallic nanoparticles. Silver nanoparticles are considering famous nanoparticles compared with other metallic nanoparticles because of their antibiotic activity against viruses, bacteria, fungi, cancers, and parasites.

Green synthesis of AgNPs was successfully done in simple, rapid, eco-friendly and a cheaper method using plant leaves extracts like *Azadirachta indica*. Rapid, simple approach was applied for synthesis of silver nanoparticles using *Azadirachta indica* aqueous leaf extract. The plant extract acts both as reducing agent as well as capping agent. To identify the compounds responsible for reduction of silver ions, the functional groups present in plant extract were investigated by FTIR. Various techniques used to characterize synthesized nanoparticles are DLS, photoluminescence, TEM and UV–Visible spectrophotometer. UV–Visible spectrophotometer showed absorbance peak in range of 436–446 nm. The silver nanoparticles showed antibacterial activities against both gram positive (*Staphylococcus aureus, Panax ginseng, Tridax procumbens, Ziziphus nummularia, Thevetia peruviana, olive (Olea europaea)*, *Cleome viscosa*, and fenugreek (*Trigonella foenum-graecum L.*), and applying them in medicine as a green drug against bacteria, fungi and tumors.

Galingale *Cyperus rotundus* belongs to Cyperaceae (sedge family). *C. rotundus* L., purple nutsedge as a common name, is a perennial weed with slender, scaly creeping rhizomes, and arising singly from the rhizomes which are about 1-3 cm. its rhizomes are externally blackish in color and white inside with a characteristic odor. Watery and ethanol crude extracts of *C. rotundus* rhizomes showed significant effects against gram-negative and gram-positive bacteria, *Candida albicans* and fungal pathogens. On the other hand, aqueous extract of *C. longous* has activity against parasitic worms.

Recently, rhizomes of *Cyperus rotundus* had anticancer effects in a recent Iraqi study, and no studies of *Cyperus* rhizomes extracts that have been reported in synthesizing silver nanoparticles. Thus we selected these galingale plant rhizomes to biosynthesize AgNPs to arise the value of inhibitory effect of *Cyperus* sp. toward human cancers in vitro.

However, silver nanoparticles have been biosynthesized from cold and hot extracts of *Cyperus* sp. galingale rhizomes and studied the nature and characteristics of these nanoparticles using UV-Visible spectroscopy, AFM, SEM, FT-IR and EDX analyses and evaluation of their anticancer activity (in vitro) against L20B cell line is a receptor for human poliovirus.
METHODOLOGY

Rhizomes samples

Fresh rhizomes of *Cyperus* sp. galingale were collected from gardens of Al-Baghdadi district west of Hit, Iraq on October 2017. The plant has identified in College of Applied Sciences-Hit using identification keys as mentioned in 16,17.

Aqueous extraction of *Cyperus* sp. (galingale) rhizomes

The cold extraction method

The fresh rhizomes of galingale were cleaned from the soil and residues of roots and washed with tap water and then by distilled water (D.W) as in figure 1. The rhizomes were peeled to remove the black cortex and then extracted. For extraction achievement, 10 g of the freshly peeled rhizomes of *Cyperus* sp. was crushed in 100 mL D.W using a mortar and stored in a freezer for 48 hr. The iced extract was slowly dissolved in the room temperature. The whitish aqueous extract was filtered using gauze and then by filter paper Whatman No.1 and centrifuged at 4000 rpm for 10 min. The supernatant was collected by a micropipette and named as cold extract solution (C). The residue was emitted. FT-IR spectrum of the crude extract was achieved to characterize and to compare with AgNPs which are formed later 6.

The hot extraction method

The fresh rhizomes were cleaned from the soil and residues of roots and washed with tap water and then by distilled water (D.W) as in figure 1. The rhizomes were peeled to remove the black cortex and then extracted. For extraction achievement, 10 g of the freshly peeled rhizomes of *Cyperus* sp. galingale was crushed in 100 mL D.W using a mortar and boiled in the magnetic stirrer hotplate for 15 min. The whitish aqueous extract was filtered using gauze and centrifuged at 4000 rpm for 15 min twice. The clear supernatant was collected by a micropipette and named as a hot extract solution (H). The residue was emitted. FT-IR spectra of the crude extract (cold and hot extracts) were done to determine the functional groups comparison with FT-IR spectra of their AgNPs which are formed later 6.

Biosynthesis of silver nanoparticles

Only 33.8 μg of AgNO₃ (its purity 99.9%, AFCO For Metal, China) was dissolved in 200 mL distilled water (D.W) using the magnetic stirrer hotplate until the completion dissolving was observed to get the final concentration 10⁻³ M. Five milliliters of series concentrations of cold and hot galingale extracts (20%, 40%, 60%, 80%, and 100%) were separately mixed with 5 mL of 10⁻³ M AgNO₃
solution in 10-mL test tubes and darkly kept at 25 °C for three days. From another hand, the second method to biosynthesize AgNPs by heating of 30 mL each crude galangale extract [cold extract (C) and hot extract (H)] was separately added drop by drop into two 500mL-flask containing 100 mL of 10^{-3} M AgNO₃ solution using magnetic stirrer hotplate at 60 °C for 1 hr. The change in the mixture color was checked and recorded each 15 min.

**Characterization of AgNPs**

Galangale-mediated synthesis of silver nanoparticles (AgNPs) using its cold and hot extracts were characterized using changes in color of the mixture, UV-Visible spectroscopy (by spectroscopy: EMC-LAB V-1100 Digital, 325-1000 nm, Germany), FT-IR (Fourier Transform Infrared) spectra, SEM (Scanning Electron Microscope), EDX, AFM (Atomic Force Microscope), and SPM (Scanning Probe Microscope) analyses.

**Anticancer efficacy**

The anticancer activity of two types of AgNPs against L20B tumor cell line was evaluated. The colorimetric cell viability MTT assay was used as mentioned by 23 and 24. Firstly, 100 μL/well of L20B cells (10^6 cell/mL) were cultured in a 96-wells tissue culture plate. Three concentrations of colloid AgNPs (50%, 75% and 100%) were applied in this test. Moreover, then 100 μL of each concentration was added within each well and incubated at 37 °C for 48 hr. after that, 10 μL of MTT solution (5 mg/mL) was added to each well and reincubated at 37 °C for 4 hr. Finally, 50 μL DMSO (dimethyl sulfoxide) was added to each well and incubated for 10 min. L20B cells were cultured in complete medium without AgNPs or the extract of *Cyperus* sp. solution as a control. The absorbance was measured for each well at 620 nm using ELISA reader. The inhibition percentage was calculated according to the equation below:

\[
\text{Growth inhibition percentage} = \left(\frac{\text{OD of control wells} - \text{OD of test wells}}{\text{OD of control wells}} \right) \times 100
\]

**Statistical Analysis**

Triplicates of growth inhibition percentage were analyzed by one-way analysis of variance using ANOVA table by SAS program version 9 (SAS Institute Inc., USA). The significance of differences was calculated using Duncan’s Multiple Range Test (DMRT). Probability value least than 5% was considered to be statistically significant.
RESULTS AND DISCUSSION

The change in color for the mixture of AgNO$_3$ and the *Cyperus* rhizomes extract from milky (hot extraction) and bright yellow (cold extraction) to the brown color was exhibited as seen in figure 1. The previous figure also is showing adsorption peaks at 410-420 nm in comparison with the crude extracts of the peeled rhizomes. Hot extract-AgNPs are showing the widest adsorption (2068 cm$^{-1}$) than cold extract-AgNPs (1800 cm$^{-1}$).

![Figure 1. Change in color and UV-Visible spectrum of the biosynthesized AgNPs from *Cyperus* rhizomes extract](image)

SEM images (figure 2) exhibited the morphology of AgNPs which ranged from spherical to irregular particles. The 3D and 2D images of AFM showed the topography of the nanoparticle’s surfaces (Figure 3). However, AFM has the advantageousness of probing the surface topography deeply. The AFM image displays the surface morphology of silver nanoparticles synthesized by *Cyperus* rhizome extracts which reveal the appearance of spherical or irregular and needle-like nanoparticles for the cold extract-AgNPs and the hot extract-AgNPs respectively. Also, roughness average is 7.65 nm and 7.11 nm; the surface area ratio is 15.3:1 and 22.5:1 and the density of summits 258 μ$^{-2}$ and 386 μ$^{-2}$ for the cold extract-AgNPs and the hot extract-AgNPs respectively.

Histogram of particle size distribution (SPM) showed the granularity distribution, volumes and averages of diameters of AgNPs (figure 3). This parameter is affirming the results of AFM images which appears smallness size of the hot extract-AgNPs comparing to the cold ones. The average diameter of the cold extract-AgNPs is 92.53 nm in comparison with the hot extract-AgNPs is 56.31 nm. Histogram of the particle size distribution of the two AgNPs was presented.
in figure 4 was clear evidence for the formation of silver particles by the percentages of Ag particles in the two treatments.

**Cold extract-AgNPs**  **Hot extract-AgNPs**

**Figure 2.** SEM of the biosynthesized silver nanoparticles

![AFM images](image2)

**Figure 3.** AFM of the colloid silver nanoparticles

![Histograms](image3)

**Figure 4.** Histogram of the particle size distribution of the biosynthesized silver nanoparticles including the cold extract-AgNPs (A) and the hot extract-AgNPs (B)
The FT-IR spectrum the cold extract (figure 5A) and the hot extract (figure 5B) showed the peak 771 cm\(^{-1}\) is due to the covalent bonding between carbon and silicon (Si-C) and other peaks 1105 cm\(^{-1}\)and 1108 cm\(^{-1}\) for cold and hot extracts respectively. These are evidence of linkage of oxygen with silicon in (Si-O). Both spectra also showed two absorption bands at 1384 cm\(^{-1}\) and 1417 cm\(^{-1}\) belong to vibrations of homogeneous and heterogeneous bends of methylene group (-CH\(_2\)) or methyl group (-CH\(_3\)) and two absorption bands at 2891 cm\(^{-1}\) and 2894 cm\(^{-1}\) for cold and hot extracts respectively, and at 2935 cm\(^{-1}\) for cold and hot extracts too. All the mentioned absorption bands belong to the previous groups which presented in the composition of amino acids, peptides or proteins. There were absorption bands at 1053 cm\(^{-1}\) and 1062 cm\(^{-1}\) proved the protein structures for cold and hot extracts respectively belong to the single bond (C-C). The spectra showed absorption bands at 1631 cm\(^{-1}\) and 1633 cm\(^{-1}\) for cold and hot extracts respectively go back to vibrations of stretching of C=C group. On another hand, the presence of C-H-containing compounds (C-H) is evidenced by the presence of two bands at 3109 and 3130 cm\(^{-1}\) for cold and hot extracts, respectively. It is confirmed that flavonoids, amino acids, peptides, proteins, polyphenols and sugars are present in the presence of a long stretching vibration of the absorption peak at 3396 and 3458 cm\(^{-1}\) for cold and hot extracts respectively. As well as two bending vibration bands at 1384 cm\(^{-1}\) for the cold extract and 1388 cm\(^{-1}\) for the cold extract belong to the hydroxyl groups (-OH); and the absorption band at 1417 cm\(^{-1}\) belongs to the group (C-O).

There are two bands at 1749, 1726 cm\(^{-1}\) for cold and hot extracts respectively, although weak. The cause of weakness is probably the multiplicity in these groups and the possibility of a succession that changes this group into a single carbon-oxygen bond. These bands go back to Carbonyl group (C=O) and this is evidence that the extracts contain flavonoids, mersatin and camphorol.
Figure 5. FT-IR of the cold extract (A) and the hot extract (B)

As for the FT-IR spectroscopy of silver nanoparticles of the hot and cold extracts, Figures 6A and 6B. The absorption bands at 1132 cm$^{-1}$ and 1120 cm$^{-1}$, the two bands at 1382 cm$^{-1}$ and 1388 cm$^{-1}$, the two bands at 1421 cm$^{-1}$ and 1419 cm$^{-1}$, and the two bands at 1622 cm$^{-1}$ and 1623 cm$^{-1}$ for the AgNPs of cold and hot extracts respectively are clear evidence of the presence of silver nanoparticles in the synthesis of the samples. These two spectra are very similar to the infrared spectrum of cold and hot extracts (figure 5) and therefore the composition is not but the insulation, clarity and beam width are better in the infrared spectrum of the nanostructures.
Figure 6. FT-IR of silver nanoparticles of the cold extract (A) and AgNPs of the hot extract (B)

The EDX spectrum of the biosynthesized AgNPs (figure 7) shows finding silver element as an indicator for the formation of silver nanoparticles from the hot extract better than the cold extract. Also, it exhibits the C, O, Cl, Si, and K elements have been presented in the used sample.
Figure 7. EDX images of the colloid AgNPs formed from the hot extract (A) and the cold one (B).

Both the cold extract-AgNPs and the hot-AgNPs were investigated against cell line of murine fibroblast cells have receptors for human polioviruses (L20B) in vitro. Figure 8 exhibited the anticancer activity of the colloid AgNPs synthesized from aqueous extracts of the peeled Galingale rhizomes. The hot-AgNPs gave better growth inhibition than the cold extract-AgNPs. The best inhibition showed by the concentration 100% of the hot-AgNPs 35.3% significantly ($p<0.01$) followed by 22.5% by the concentration of 75% of the hot-AgNPs. The concentration 100% of the cold-AgNPs exhibited 22.4% then decreased to 17.9% by the concentration of 75% of the cold-AgNPs. The concentration 50% did not show any inhibitory effects as in the crude extracts of Cyperus rhizomes.
The change in color for the mixture of AgNO₃ and the Cyperus rhizomes extract from milky (hot extraction) bright yellow (cold extraction) to the brown color is a sign for the formation silver nanoparticles as seen in figure 1. The density of brown color is due to excitation of surface plasmon vibrations in the silver nanoparticles, and that is confirmed using UV-Visible spectra. Hot extract-AgNPs are showing the widest adsorption (2068 cm⁻¹) than cold extract-AgNPs (1800 cm⁻¹), because of the resonance wavelength of silver nanoparticles has strong depending on Ag atoms, size and morphology of particles.

SEM, AFM and Histogram of particle size distribution (SPM) were used to confirm the nature, topography, morphology of the silver nanoparticles. SEM images (figure 2) exhibited the morphology of AgNPs which ranged from spherical to irregular particles. The shape of silver nanoparticles agreed with many recent studies. The 3D and 2D images of AFM showed the topography of the nanoparticles surfaces (figure 3). Atomic Force Microscope is a useful tool to study different morphological parameters. AFM images as in figure 3 show high-resolution topography and the silver nanoparticles can be visualized under the dry condition.

However, AFM has the advantageousness of probing the surface topography deeply due to its lateral and trial dimensions in nanometer scale resolution. The AFM image displays the surface morphology of silver nanoparticles synthesized by Cyperus rhizome extracts which reveal the appearance of spherical or irregular and needle-like nanoparticles for the cold extract-AgNPs and
the hot extract-AgNPs respectively. Also, roughness average, the surface area ratio and the density of summits are evidence to form the smallest nanoparticles for AgNPs formed from the hot extract of *Cyperus* rhizome and more summits by high surface area ratio.

Histogram of particle size distribution (SPM) showed the granularity distribution, volumes and averages of diameters of AgNPs (figure 3). This parameter is affirming the results of AFM images which appears smallness size of the hot extract-AgNPs comparing to the cold ones. The average diameter of the cold extract-AgNPs is 92.53 nm in comparison with the hot extract-AgNPs is 56.31 nm. The reason for this phenomenon is related to the extraction technique which means the heating process during preparation of the herbal extracts leads to destroying active ingredients. Then the interaction of the finer biomolecules with silver ions leads to synthesize finer nanoparticles. Histogram of the particle size distribution of the two AgNPs was presented in Figure 4 was clear evidence for the formation of silver particles by the percentages of Ag particles in the two treatments. All sizes of the biosynthesized AgNPs in the colloids are lesser than 100 nm which is considered a definite proof for the formation of AgNPs.

Fourier Transform Infrared spectrum (FT-IR) was used to determine the chemical structure and the functional groups. In cold and hot extracts, the similarities were observed in the peak sites. The FT-IR spectrum the cold extract (figure 5A) and the hot extract (figure 5B) confirms the presence of compensated aromatic rings all of which go back to the amino acids, peptides and proteins, amintoflavone and flavonoids see figure 9, poly hydroxyl compounds such as myristin, albicaine, camphorol see figure 10, alkene compounds such as lemons, cocaine and mirentol see figure 11.

**Figure 9.** Structures of amintoflavone and flavonoids compounds in *Cyperus* sp. rhizomes
The absorption bands at 2891 cm\(^{-1}\) and 2894 cm\(^{-1}\) for cold and hot extracts respectively, and at 2935 cm\(^{-1}\) for cold and hot extracts also belong to vibrations of homogeneous and heterogeneous stretching of a methylene group (-CH\(_2\)) or a methyl group (-CH\(_3\)) \(^{36}\). This research includes synthesis of new heterocyclic derivatives of disubstituted 1,3-oxazepine-5-one. Azomethine compounds (N1-N5). The spectra showed absorption bands at 1631 cm\(^{-1}\) and 1633 cm\(^{-1}\) for cold and hot extracts respectively go back to vibrations of stretching of C=C group belongs to the alkene compounds and the successive double bonds in the benzene ring in the aromatic structures \(^{37}\). As well as two bending vibration bands at 1384 cm\(^{-1}\) for the cold extract and 1388 cm\(^{-1}\) for the cold extract belong to the hydroxyl groups (-OH); and the absorption band at 1417 cm\(^{-1}\) due to the stretching vibration of the group (C-O) \(^{38}\). The absorption bands 582-578 cm\(^{-1}\) and 688-686 cm\(^{-1}\) for the cold and hot extracts respectively indicate to the amide group (O=C=N-H), which binds two consecutive amino acids in the synthesis of peptides or proteins. The bands at 3267-3271 cm\(^{-1}\) and 3417-3367 cm\(^{-1}\) indicate for the presence of the amine group (-NH\(_2\)) in the synthesis of amino acids, peptides and proteins for cold and hot extracts respectively \(^{32,39}\). The presence of the carboxylic group in
amino acids, peptides and proteins are the appearance of the wide absorption range (2400-3600 cm⁻¹) for both extracts and maybe the presence of a carboxylic group (-COOH) in mono acidic saccharides compounds such as glucuronic acid 40–43 3-oxazepin-5(1H see figure 12.

![Structures of mono acidic saccharides compounds in Cyperus sp. rhizomes](image)

**Figure 12.** Structures of mono acidic saccharides compounds in Cyperus sp. rhizomes

The FT-IR spectra of silver nanoparticles of the hot and cold extracts (Figures 6A and 6B) showed clear evidence of the presence of silver nanoparticles in the synthesis of the samples because in a study on mushroom found that the silver nanostructure binds with the hydrocarbon’s compounds. It shows four packages located nearby and within the ranges listed 44. These two spectra are very similar to the infrared spectrum of cold and hot extracts and therefore the composition is not, but the insulation, clarity and beam width are better in the infrared spectrum of the nanostructures. The spectrum of silver nanoparticles (Figure 6B) was observed to be similar to Figure 5B regarding the sites of the functional groups, but the appearance of the bands was more apparent and better. That may be due to the presence of silver atoms with a high surface area that allows all the atoms with negative electrical and containing pairs of electrons not involved as in the mushroom extract to participate in the silver nanoparticles sample containing the atoms of silver spread well. It is known that the silver atoms contain 47 electrons, so contain in its fifth shell one electron in the second level 5s. Thus, the other secondary levels are 5p containing three orbitals, 5d containing five orbitals and 4f containing seven empty orbitals and can accommodate electronic pairs coming from atoms with good negative electrical. The oxygen atom found in the formation of mono crystalline polysaccharides in the form of (-OH) in acid sugars or in the form of (C-OO) or in the form of carbonyl (C=O) in male compounds previously, the link is as follows (Ag-OR) where R is mono crystalline or polyunsaturated sugar or amino acid or Peptide, protein, phenols or flavonoids. Another example of good electrolyte atom is the atom of nitrogen in the form of (=NH) in arginine or the form of (-NH₂) or (-NH-C=O) in peptides and proteins. The association is as follows (Ag-NR) (R) is an amino acid, peptide or protein,
and the other electrolytic atom is the sulfur atom found in the synthesis of amino acids, peptides and proteins in the form of (-S-) and in the form of (-SH) (Ag-SR) where R is an amino acid or peptide or protein. FT-IR exhibited that the presence of carbonyl (C=O) and hydroxyl groups (-OH) in the extract of *Cyperus* sp. can reduce and stabilize silver nanoparticles.

Carbon and oxygen are presented in the EDX graph (Figure 7) due to the organic molecules which found in the extract of the mushroom. These biomolecules may be amino acids or proteins or polysaccharides or polyphenols which capped the silver nanoparticles as capping and stabilizing agents. The presence of the elemental Ag can be seen in the EDX graph (figure 7) that indicates the reduction of Ag ions to elemental silver. Further, Chlorine is also observed due to the un-reacted precursors of AgNO$_3$.

The silver nanoparticles formed from these rhizomes are exhibiting unique physicochemical and biological activities thus they have the inhibitory role. The reason of the high inhibitory effects of the hot extract-AgNPs returns to smallness the average of size of these AgNPs (56.31 nm in diameter) in comparison to the average of size of the cold extract-AgNPs (92.53 nm) as in Figure 4 that lead to increase the surface area ratio of the hot extract-AgNPs as AFM in Figure 3.

This study proved the rhizome-mediated synthesis of AgNPs using the cold and hot watery rhizomes extracts of *Cyperus* sp. FT-IR exhibited that the presence of carbonyl and hydroxyl groups in the extract of *Cyperus* sp. can reduce and stabilize silver nanoparticles. EDX, SEM, and AFM analyses were confirmed that the biosynthesized silver nanoparticles were spherical or irregular in shape with the average diameter of the hot extract-AgNPs is 56.31 nm in comparison with the cold extract-AgNPs is 92.53 nm. EDX images indicate to form silver nanoparticles from the hot extract better than the cold one. The synthesized silver nanoparticles were tested against cancer cell line L20B. The hot extract-AgNPs plays a suitable role against mouse cell line (L20B) which have receptors for polioviruses better than the cold extract-AgNPs. The best inhibition showed by the concentration 100% of the hot-AgNPs 35.3% significantly ($p<0.01$).

**ACKNOWLEDGEMENTS**

The author and co-author are thanking the staff of Department of Ecology, College of Applied Sciences-Hit in University of Anbar to complete project No. 3/122 on 15 Oct 2017. Special thanks to President of the University Prof. Dr. Khalid Battal Najim and Dean of the College, Prof. Dr. Tahseen Ali Zaidan for their continuous support in publishing the research in the certified international journal. Another thank is introducing to the University of Baghdad for achieving the AFM nanophotographic.
